Four separate CTA requirements

Assessment	Required evidence	Current implementation
Safety	Acceptable normal-tissue RNA / protein evidence across Vital, Protected and Manageable compartments.	Active. Only this assessment can supply Unsafe evidence. Manageable excess blocks CTA under the current rules.
Cancer expression	Expression in at least one measured cancer sample.	Active. At least 2 in native TPM or HPA pTPM. One sample qualifies. No tumor-versus-normal ratio.
Adult restriction	A qualifying reproductive or developmental signal exceeds supported adult normal RNA in its own native unit.	Active. Compare with Vital / Protected / Manageable. Exclude Reproductive / Disposable. CP10K stays safety-only.
Reproductive / developmental association	Affirmative expression in reproductive, placental, embryonic or fetal contexts.	Active quantified routes. Reproductive or supported developmental expression can qualify.

CTA: acceptable safety AND cancer expression AND adult restriction AND reproductive/developmental association, with adequate evidence.
Only safety can establish Unsafe. Other failed or missing requirements block CTA. Neither needs its measured-profile definition; other cases remain unassigned.
